

AlphaFold 3 - Sequencing Talk

- They simplified noise + the clash loss, so inactive structures don't matter
- The diffusion model is trained on AlphaFold 2 models (Some hallucination)
- Not entirely fixed yet
- MSAs only 4 blocks with the new MSA module and the purchase attention
- AlphaFold 3 is a much faster (lighter weight) model (lower sequence are possible)
- Pairwise-weighted averaging $\rightarrow$ (lighter weight) instead of original attention

(John Walker) - For antibodies, multiple views or AlphaFold 3 is needed to get the highest confidence

↳ AP sample - Diffusion model $\rightarrow$ better with constraints from pairwise, improved (confidence) domain

- AlphaFold 3 $\rightarrow$ 2 jobs per day (but you can take extra accounts)
- Good with acids, good (Good atoms)

- Post-hoc structural use only

May have changed

- Lipids can stabilize some structural and also change lipid bilayers

- Multimeric complexes may improve

- Correlation is computed in the cross-predicted graph

- ↳ It's computed by MSA and

$$W = (1 - \lambda) \cdot \text{inv}(\text{cov}(X + \lambda I))$$

- ↳ Direct Correlation Analysis, you need to normalize the weights $X > S$

- Labels are "reduced" to a contact map

$$C = \text{cov}(C)$$

$$C_{ij} = \text{val}_{ij} \cdot \text{eigh}(C)$$

$$C = \text{val} \cdot \text{vec} C @ \text{vec} C^T$$

$$C^{-1} = (\text{vec} C @ \text{vec} C^T) / \text{val}$$

- Inverse = downweighting the largest eigenvalue of the covariance matrix

- Eigen decomposition can be computed via power iteration

- Random eigen-vectors can be approximated via random matrix multiplication

$$\text{vec} C \sim C @ \text{random}$$

Code:

$$\text{vec} = \text{msa} \cdot \text{reshape}(N, -1) \quad \text{for } i \text{ in range}(C_{\text{seq}}): \text{FORM}$$

$$\text{vec} = \text{vec} - \text{vec} \cdot \text{mean}(C) \quad \text{pair} = (\text{vec}[i] @ \text{vec}[j] / \text{vec} \cdot \text{shape}[0])$$

If random returns

$$\text{params} = \text{np.random.normal}(\text{size} = (C_{\text{seq}} \cdot \text{shape}[0], 1))$$

$$\text{param}_r = \text{pair} @ \text{params} \quad \text{params} = [\text{np.sqrt}(C), \text{np.sqrt}(C(\text{params}).\text{sum}())]$$
